Science and mission planning questions:

- 1 What **observational records** are needed (in space and time) to maximize terrestrial snow experimental utility?
- 2 How might observations be **coordinated** (in space and time) to maximize this utility?
- 3 What is the **additional utility** associated with an additional observation?
- 4 How can future **mission costs be minimized** while ensuring Science requirements are fulfilled?

- Global snow mission will require **evidence of achievable science** via OSSE ... or some other means
- NASA LIS provides **"nature run"** plus assimilation framework
- TAT-C provides **spatiotemporal sub-sampling** of observations, including **cost estimates and risk assessments**
- **Machine learning** maps model state(s) into observation space (i.e., T_b and σ_0)
 - Enables integration of T_b , σ_0 , and δh in geophysical realm (i.e., SWE and snow depth)
 - **Multiple frequencies/polarizations/observations** allow for flexibility and modularity in DA framework
- Snow **OSSE is on-going** → open to ideas + suggestions!

For parameters $C > 0$ and $\varepsilon > 0$, the **standard (primal)** form is:

$$\begin{aligned} & \underset{\mathbf{w}, \delta, \xi, \xi^*}{\text{minimize}} && \frac{1}{2} \langle \mathbf{w} \cdot \mathbf{w} \rangle + C \sum_{i=1}^m (\xi_i + \xi_i^*) \\ & \text{subject to} && \langle \mathbf{w} \cdot \phi(\mathbf{x}_i) \rangle + \delta - z_i \leq \varepsilon + \xi_i \\ & && z_i - \langle \mathbf{w} \cdot \phi(\mathbf{x}_i) \rangle - \delta \leq \varepsilon + \xi_i^* \\ & && \xi_i, \xi_i^* \geq 0, i = 1, 2, \dots, m. \end{aligned}$$

where m is the available number of T_b measurements in time (for a given location in space), z_i is a T_b measurement at time i , and ξ and ξ^* are slack variables.

Primal optimization is commonly solved in **dual form** as:

$$\begin{aligned}
 &\underset{\alpha_i, \alpha_i^*}{\text{minimize}} && \frac{1}{2} \sum_{i,j=1}^m (\alpha_i - \alpha_i^*) (\alpha_j - \alpha_j^*) \langle \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j) \rangle \\
 &&& + \varepsilon \sum_{i=1}^m (\alpha_i + \alpha_i^*) - \sum_{i=1}^m z_i (\alpha_i - \alpha_i^*) \\
 &\text{subject to} && \sum_{i=1}^m (\alpha_i - \alpha_i^*) = 0, \\
 &&& \alpha_i, \alpha_i^* \in [0, C], \quad i = 1, 2, \dots, m
 \end{aligned}$$

where α_i and α_i^* are Lagrangian multipliers, $\langle \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j) \rangle$ is the inner dot product of $\phi(\mathbf{x}_i)$ and $\phi(\mathbf{x}_j)$, ε is the specified error tolerance, and C is a positive constant that dictates a penalized loss during training.
